Q: SPLItem.File and SPLItem.Folder are null I am using Sharepoint 2010 and I have the following method that should return the data of a simple list as string. public static string GetListData(Guid listId, string folder) { var list = GetList(listId); var folderData = list.GetFolder(folder); return (folderData!= null)? folderData.Files.ToString() : ""; } This code does not return any data when I test it. So I checked the list with SPD. And I realized that the files and folders of the list are null! folderData.files.Count == 0 // true folderData.folders.Count == 0 // true Are there any reasons why these values are null? Thank a lot for your help. A: It turns out that the folderData does not automatically contain the files that the user just created through the list. You must request the folder using the folder ID from the SPLItemCollection returned by GetFolder var folderData = list.GetFolder(folderId); Q: How to translate "if you only knew" I would like to translate the idiomatic phrase "if you only knew". How do you phrase it in other languages, for example Spanish? A: In Spanish you can say "estaría contento" (with "estar" meaning "to be"). Example: "Tú lo tienes que aprender. No estarías contento de nada que sepas de eso" A: I think the word you're looking for is Dolor. Dolor = If you only knew the pain. Wireless/Cellular networking technologies such as the 3GPP Long Term Evolution (LTE) and the LTE Advanced (LTE-A) represent an important technological advancement in wireless telecommunication, which provide faster downloads of data and significantly higher data capacity than existing second generation wireless communication protocols. LTE and LTE-A are scheduled to achieve the objective of providing data rates of up to 100 Mbps for mobile broadband users. The LTE-A protocol typically includes Orthogonal Frequency Division Multiplexing (OFDM) as the radio access technology used for the downlink transmissions and Single Carrier-Frequency Division Multiple Access (SC-FDMA) as the radio access technology used for the uplink transmissions. In both cases, multiple base stations (which may be referred to as "eNB") transmit data to and receive data from a plurality of user devices (which may be referred to as "UE"). Each UE transmits and receives data according to an assigned schedule, which enables each UE to transmit data to and receive data from the base stations in a time division multiplexed (TDM) manner. Each base station schedules data by transmitting a plurality of data packets to be transmitted to a corresponding plurality of UEs. For example, an LTE or LTE-A base station may transmit data to one or more UEs according to the following manner: the base station receives and converts the data into an appropriate format for transmission; the base station generates a corresponding scheduling request message that includes an indication of the data to be transmitted and schedule information for the corresponding data; the base station transmits the scheduling request message to the UE by using a Random Access Channel (RACH); the UE detects the scheduling request message, decodes the scheduling request message, and determines the base station from which the scheduling request message originated. The UE may then respond to the scheduling request message and provide scheduling information for the data. The scheduling request message may be transmitted using an RACH or a contention based random access channel (CB-RACH). For example, a random access channel (RACH) resources are not associated with any particular UE, so each UE must transmit a random access message and wait for the responses. In the LTE and LTE-A protocols, a predetermined (e.g., long) random access preamble sequence is assigned to a UE, but a different random access preamble sequence can be used for each RACH transmission by the UE. When a UE senses its assigned RACH, it selects
